CP-226: Computer Architecture

Lecture 4 (01 Feb 2013)

CADSL

Performance and Cost

- Which of the following airplanes has the best performance?

<u>Airplane</u>	<u>Passengers</u>	<u>Range (mi)</u>	<u>Speed (mph)</u>
Boeing 737-100	101	630	598
Boeing 747	470	4150	610
BAC/Sud Concorde	132	4000	1350
Douglas DC-8-50	146	8720	544

- How much faster is the Concorde vs. the 747
- How much bigger is the 747 vs. DC-8?

Performance and Cost

- Which computer is fastest?
- Not so simple
 - Scientific simulation – FP performance
 - Program development – Integer performance
 - Database workload – Memory, I/O

Performance of Computers

- Want to buy the fastest computer for what you want to do?
 - Workload is all-important
 - Correct measurement and analysis
- Want to design the fastest computer for what the customer wants to pay?
 - Cost is an important criterion

Defining Performance

- What is important to whom?
- Computer system user
 - Minimize elapsed time for program = $\text{time_end} - \text{time_start}$
 - Called **response time**
- Computer center manager
 - Maximize completion rate = $\# \text{jobs/second}$
 - Called **throughput**

Response Time vs. Throughput

- Is throughput = $1/\text{av. response time}$?
 - Only if NO overlap
 - Otherwise, throughput $> 1/\text{av. response time}$
 - E.g. a lunch buffet – assume 5 entrees
 - Each person takes 2 minutes/entrée
 - Throughput is 1 person every 2 minutes
 - BUT time to fill up tray is 10 minutes
 - Why and what would the throughput be otherwise?
 - 5 people simultaneously filling tray (overlap)
 - Without overlap, throughput = $1/10$

What is Performance for us?

- For computer architects
 - CPU time = time spent running a program
- Intuitively, bigger should be faster, so:
 - Performance = $1/X$ time, where X is response, CPU execution, etc.
- Elapsed time = CPU time + I/O wait
- We will concentrate on CPU time

Improve Performance

- Improve (a) response time or (b) throughput?
 - Faster CPU
 - Helps both (a) and (b)
 - Add more CPUs
 - Helps (b) and perhaps (a) due to less queueing

Performance Comparison

- Machine A is n times faster than machine B iff $\text{perf}(A)/\text{perf}(B) = \text{time}(B)/\text{time}(A) = n$
- Machine A is $x\%$ faster than machine B iff
 - $\text{perf}(A)/\text{perf}(B) = \text{time}(B)/\text{time}(A) = 1 + x/100$
- E.g. $\text{time}(A) = 10\text{s}$, $\text{time}(B) = 15\text{s}$
 - $15/10 = 1.5 \Rightarrow A$ is 1.5 times faster than B
 - $15/10 = 1.5 \Rightarrow A$ is 50% faster than B

Breaking Down Performance

- A program is broken into instructions
 - H/W is aware of instructions, not programs
- At lower level, H/W breaks instructions into cycles
 - Lower level state machines change state every cycle
- For example:
 - 1GHz Snapdragon runs 1000M cycles/sec, 1 cycle = 1ns
 - 2.5GHz Core i7 runs 2.5G cycles/sec, 1 cycle = 0.25ns

Iron Law

$$\text{Processor Performance} = \frac{\text{Time}}{\text{Program}}$$

$$= \frac{\text{Instructions}}{\text{Program}} \times \frac{\text{Cycles}}{\text{Instruction}} \times \frac{\text{Time}}{\text{Cycle}}$$

(code size) (CPI) (cycle time)

Architecture --> Implementation --> Realization

Compiler Designer

Processor Designer

Chip Designer

Iron Law

- Instructions/Program
 - Instructions executed, not static code size
 - Determined by algorithm, compiler, ISA
- Cycles/Instruction
 - Determined by ISA and CPU organization
 - Overlap among instructions reduces this term
- Time/cycle
 - Determined by technology, organization, clever circuit design

Our Goal

- Minimize time which is the product, NOT isolated terms
- Common error to miss terms while devising optimizations
 - e.g. ISA change to decrease instruction count
 - BUT leads to CPU organization which makes clock slower
- Bottom line: terms are inter-related

Other Metrics

- MIPS and MFLOPS
- MIPS = instruction count/(execution time x 10^6)
= clock rate/(CPI x 10^6)
- But MIPS has serious shortcomings

Problems with MIPS

- E.g. without FP hardware, an FP op may take 50 single-cycle instructions
- With FP hardware, only one 2-cycle instruction

- **Thus, adding FP hardware:**

- CPI increases (why?)
- Instructions/program decreases (why?)
- Total execution time decreases

$$50/50 \Rightarrow 2/1$$

$$50 \Rightarrow 1$$

$$50 \Rightarrow 2$$

$$50 \text{ MIPS} \Rightarrow 2 \text{ MIPS}$$

- BUT, MIPS gets worse!

Problems with MIPS

- Ignores program
- Usually used to quote peak performance
 - Ideal conditions => guaranteed not to exceed!
- When is MIPS ok?
 - Same compiler, same ISA
 - E.g. same binary running on AMD Phenom, Intel Core i7
 - Why? Instr/program is constant and can be ignored

Other Metrics

- MFLOPS = FP ops in program / (execution time x 10^6)
- Assuming FP ops independent of compiler and ISA
 - Often safe for numeric codes: matrix size determines # of FP ops/program
 - However, **not always safe**:
 - Missing instructions (e.g. FP divide)
 - Optimizing compilers
- Relative MIPS and normalized MFLOPS
 - Adds to confusion

Rules

- Use ONLY Time
- Beware when reading, especially if details are omitted
- Beware of Peak
 - “Guaranteed not to exceed”

Iron Law Example

- Machine A: clock 1ns, CPI 2.0, for program x
- Machine B: clock 2ns, CPI 1.2, for program x
- Which is faster and how much?

Time/Program = instr/program x cycles/instr x sec/cycle

$$\text{Time(A)} = N \times 2.0 \times 1 = 2N$$

$$\text{Time(B)} = N \times 1.2 \times 2 = 2.4N$$

$$\text{Compare: } \text{Time(B)}/\text{Time(A)} = 2.4N/2N = 1.2$$

- So, Machine A is **20%** faster than Machine B for this program

Iron Law Example

Keep clock(A) @ 1ns and clock(B) @ 2ns

For equal performance, if $CPI(B)=1.2$, what is $CPI(A)$?

$$\text{Time}(B)/\text{Time}(A) = 1 = (N \times 2 \times 1.2) / (N \times 1 \times CPI(A))$$
$$CPI(A) = 2.4$$

Iron Law Example

- Keep $CPI(A)=2.0$ and $CPI(B)=1.2$
- For equal performance, if $clock(B)=2ns$, what is $clock(A)$?

$$\begin{aligned} \text{Time}(B)/\text{Time}(A) &= 1 = (N \times 2.0 \times \text{clock}(A)) / (N \times 1.2 \times 2) \\ \text{clock}(A) &= 1.2ns \end{aligned}$$

Which Programs

- Execution time of what program?
- Best case – you always run the same set of programs
 - Port them and time the whole workload
- In reality, use benchmarks
 - Programs chosen to measure performance
 - Predict performance of actual workload
 - Saves effort and money
 - Representative? Honest? Benchmarking...

How to Average

	Machine A	Machine B
Program 1	1	10
Program 2	1000	100
Total	1001	110

- One answer: for total execution time, how much faster is B? **9.1x**

How to Average

- Another: arithmetic mean (same result)
- Arithmetic mean of times:
- $AM(A) = 1001/2 = 500.5$
- $AM(B) = 110/2 = 55$
- $500.5/55 = 9.1x$
- Valid only if programs run equally often, so use weighted arithmetic mean:

$$\left\{ \sum_{i=1}^n time(i) \right\} \times \frac{1}{n}$$

$$\left\{ \sum_{i=1}^n (weight(i) \times time(i)) \right\} \times \frac{1}{n}$$

Other Averages

- E.g., 30 mph for first 10 miles, then 90 mph for next 10 miles, what is average speed?
- Average speed = $(30+90)/2$ **WRONG**
- Average speed = total distance / total time
 $= (20 / (10/30 + 10/90))$
 $= 45 \text{ mph}$

Harmonic Mean

- Harmonic mean of rates =

$$\frac{n}{\left\{ \sum_{i=1}^n \frac{1}{rate(n)} \right\}}$$

- Use HM if forced to start and end with rates (e.g. reporting MIPS or MFLOPS)
- Why?
 - Rate has time in denominator
 - Mean should be proportional to inverse of sums of time (not sum of inverses)
 - See: J.E. Smith, “Characterizing computer performance with a single number,” CACM Volume 31 , Issue 10 (October 1988), pp. 1202-1206.

Dealing with Ratios

	Machine A	Machine B
Program 1	1	10
Program 2	1000	100
Total	1001	110

- If we take ratios with respect to machine A

	Machine A	Machine B
Program 1	1	10
Program 2	1	0.1

Dealing with Ratios

- Average for machine A is 1, average for machine B is 5.05
- If we take ratios with respect to machine B

	Machine A	Machine B
Program 1	0.1	1
Program 2	10	1
Average	5.05	1

- Can't both be true!!!
- Don't use arithmetic mean on ratios!

Geometric Mean

- Use geometric mean for ratios
- Geometric mean of ratios =

$$\sqrt[n]{\prod_{i=1}^n ratio(i)}$$

- Independent of reference machine
- In the example, GM for machine a is 1, for machine B is also 1
 - Normalized with respect to either machine

But...

- GM of ratios is not proportional to total time
- AM in example says machine B is 9.1 times faster
- GM says they are equal
- If we took total execution time, A and B are equal only if
 - Program 1 is run 100 times more often than program 2
- Generally, GM will mispredict for three or more machines

Summary

- Use AM for times
- Use HM if forced to use rates
- Use GM if forced to use ratios

- Best of all, use unnormalized numbers to compute time

Benchmarks: SPEC2000

- System Performance Evaluation Cooperative
 - Formed in 80s to combat benchmarking
 - SPEC89, SPEC92, SPEC95, SPEC2000
- 12 integer and 14 floating-point programs
 - Sun Ultra-5 300MHz reference machine has score of 100
 - Report GM of ratios to reference machine

Benchmarks: SPEC CINT2000

Benchmark	Description
164.gzip	Compression
175.vpr	FPGA place and route
176.gcc	C compiler
181.mcf	Combinatorial optimization
186.crafty	Chess
197.parser	Word processing, grammatical analysis
252.eon	Visualization (ray tracing)
253.perlbmk	PERL script execution
254.gap	Group theory interpreter
255.vortex	Object-oriented database
256.bzip2	Compression
300.twolf	Place and route simulator

Benchmarks: SPEC CFP2000

Benchmark	Description
168.wupwise	Physics/Quantum Chromodynamics
171.swim	Shallow water modeling
172.mgrid	Multi-grid solver: 3D potential field
173.applu	Parabolic/elliptic PDE
177.mesa	3-D graphics library
178.galgel	Computational Fluid Dynamics
179.art	Image Recognition/Neural Networks
183.quake	Seismic Wave Propagation Simulation
187.facerec	Image processing: face recognition
188.amp	Computational chemistry
189.lucas	Number theory/primality testing
191.fma3d	Finite-element Crash Simulation
200.sixtrack	High energy nuclear physics accelerator design
301.apsi	Meteorology: Pollutant distribution

Thank You
